FOREWORD

This second technical report on Population Based Long term Epidemiological studies for the duration 1996-2010 marks the successful completion of twenty five years of scientific data collection by the staff of National Institute for Research in Environmental Health (previously with Centre for Rehabilitation Studies). The first phase of data collection was carried out during 1985-1994 which was previously published in the form of first technical report.

During 25 years of its operation, the study has collected enormous data through periodic surveys of the community. The detailed methodology, results and conclusions are explained in this report. It gives me great pleasure to note that lot of efforts have been made by the staff of the study team in collection and analysis of data to bring out the report in this final form.

The objective of the initial set up at Bhopal after the industrial accident and environmental disaster in December 1984 was to develop a scientific, rational and therapeutic approach to help the MIC affected individuals.

This technical report consolidates the outcome of the second phase of the long-term follow-up of this cohort study. The report may have immense importance in terms of understanding the evolution of late effects of MIC exposure.

I hope that the publication of this technical report would be taken as another achievement by this team and would serve as a baseline for next phase of research programme of National Institute for Research in Environmental Health (NIREH), an institute created to eventually become a centre of excellence and also emerge as a National Institute to head the research in environmental health.

Vishwa Mohan Katoch

(V.M Katoch)

Preface

On the night of 2nd/3rd December 1984, world's worst industrial accident took place at the pesticide plant owned by an American Multinational, the Union Carbide Corporation at Bhopal, Madhya Pradesh, India. Approximately, 40 tons of highly toxic liquid Methyl Isocyanate (MIC) stored in tank 610 suddenly escaped in a gaseous form into the atmosphere following entry of water into the tank. This occurred around midnight when the ambient temperature was below 10° Celsius. The tank burst out emitting a thick cloud of deadly fumes. The gases spilled over houses, streets situated in areas inhabited by approximately, 500,000 people. A large number of deaths, estimated to be about 2500, occurred in the exposed population.

Ironically, despite the existence of the Union Carbide, pesticide manufacturing plant since 1969, at the time of the disaster no information on the toxicity of MIC was or could be provided by the Union Carbide management, nor were there any contingency plans for disaster management. Immediate observations on the dead (post mortem) and the pattern of morbidity amongst the survivors indicated that although lung and eyes seemed the main target organs, multiorgan involvement in the survivors was also to be expected. Certain pertinent questions were raised in this regard. How long will the effects last? What permanent disabilities are likely to be expected? What is the future of for these victims and of their off springs?

Dr. V. Ramalingaswamy, the then Director General and Dr. S. Sriramachari, the then Additional D.G. of the Indian Council of Medical Research (ICMR), New Delhi, initiated the entire research set up at Bhopal. They visualized the far reaching impact of the toxic gas(es) on various organ systems. Within a month of the disaster, in January 1985, the ICMR geared up its resources to undertake the gigantic task of identifying the toxic gaseous products and study their effects on human health. The facilities available for research at Bhopal were limited both in terms of manpower and equipment. Therefore, the task to create technical know-how and research infrastructural facilities at Bhopal was undertaken. A number of eminent scientists from all over the country were drawn to contribute in this endeavor. Twenty main research projects on various aspects of the gas injury ranging from epidemiology to molecular biology were initiated. ICMR established Bhopal Gas Disaster Research Centre (BGDRC) at Gandhi Medical College to coordinate research activities.

Further, in addition to several ICMR institutes, many prominent medical research institutions spread over the country extended timely help and co-operation.

Of the various projects initiated, a core project on epidemiological aspects of toxic gas exposure was undertaken. A cohort of 80,021 persons residing in 36 municipal wards of Bhopal, exposed with toxic gas was registered. Another cohort of 15,931 persons was also registered from an area where history and symptoms due to the gas exposure were not reported. Five Community Health Clinics were set up in the exposed areas and one in the control area.

This became a core project from which samples for other specific studies were taken and linkages between these studies were established. The field teams collected morbidity and mortality data through home visits.

The first Technical Report on "Population based Long-term Epidemiological Study (1985-1994)" was published which reveal that those exposed to toxic gas for a long period, after the exposure, continued to suffer from multisystem involvement like respiratory, ophthalmic and gastrointestinal disorders.

The details of methodology, result and conclusions of the project on "Population Based Long Term Epidemiological Studies on the Health Effects of Bhopal Toxic Gas Exposure 1996-2010)" are presented here in the form of a Technical Report.

Prof. Manoj Pandey
Director Incharge, NIREH

Acknowledgements

The project on “Population Based Long Term Epidemiological Studies on the Health Effects of Bhopal Toxic Gas Exposure” has been conducted for more than two decade and large numbers of scientists have contributed in these studies.

It is worthy to note the contribution made by Late Dr. V. Ramalingaswamy, and Prof. N.K. Ganguly Former Director General's, ICMR. Late Dr. S. Sriramachari, Additional Director General and Dr. Usha K. Luthra, Former Additional Director General and Chief NCD, Late Dr. C.R. Ramchandran, Chief NCD, Late Dr. A.K. Prabhakar, NCD New Delhi, and eminent scientific community to the most valuable contribution made by Late Dr. S. N. Sharma, HOD, Deptt. of P.S.M, GMC and first Principal Investigator of the Project, Late Dr. M. P.Dwivedi, Former Director BGDR,ICMR, Bhopal and Principal Investigator of this Project.

Thanks are due to Dr. V. M. Katoch, Director General, ICMR, Dr. Padam Singh Former Additional Director General, Dr. Bela Shah, Scientist-G, Head NCD, ICMR and Dr. Arvind Pandey, Director NIMS, Dr. D. K. Shukla, Scientist-F, ICMR, Dr. R. K. Gupta, Scientist-F and Dr. Atul Juneja, Scientist –D, NIMS, New Delhi and other Scientists of Indian Council Of Medical Research for technical guidance.

With gratitude, we extend our sincere thanks to members of Advisory Committee and Review Committee who have greatly contributed with their valuable time for guidance of this study. Our sincere gratitude is due to all the people who extended their cooperation and time for participation in this study over a protracted period of time.

The Report could be brought into proper shape, proper content was possible only because of extensive guidance and active cooperation made by Dr. Padam Singh, Dr. P. S. S. Sundar Rao, Dr. D. C. S. Reddy, Dr. V. K. Vijayan, Dr. H. R. Rajmohan, Dr. B. Mishra, Dr. J. S. Thakur, Dr. S.N. Dwivedi, Dr. S.K. Jain and Dr. R.C. Sharma.

I am also highly thankful to Mr. K.K. Dubey, Director, Kamla Nehru Hospital, and Deputy Secretary Gas Rahat, Bhopal whose guidance have been continuously encouraging to complete the task within time. I would like to extend my thanks to my colleagues Dr. Sushil Singh and Mrs. Moina Sharma, Dr. B. S. Panwar, Dr. K. K. Soni, Dr. U. M. Rao, Dr. R. Galgalekar and Mr. Sanjay Khare without their active contribution it could never been possible to shape this report in present form.

I would like to express my gratitude to all my colleagues of epidemiological study for their continuous efforts in collection of information from registered cohort I would also like to express my thanks to Mrs. Premalata Maheshwari, and Mrs. Gaurie Shrivastava, Research Assistants who were recently retired after making immense contribution to the study.

I must acknowledge the contribution of our three staff members, Dr. Om Prakash Tiwari, Assistant Research Officer (Computer), Mr. Sudeep Shrivastava, Research Assistant, and Mr. M. P Tiwari, Field Attendant whose untimely demise has caused severe loss in the research activities of the Centre.

I am also thankful to Mr. Sudhir Shrivastava, Mr. Krishnadas V. K., Mr. R. K. Varma, Mr.

Mohan Waldhurkar, Mrs. Anitha S. Pillai and Mr. C. S. Pillai, Mr. Sunil Sharma, Mr. Anand Kori, Mr. Rajendra Pandey, Mr. Mateen Khan, Mrs. Meena Chaturvedi, Mr. Vijay Singh and Mrs. Swapna Azhar for their continuous assistance in the preparation of this report.

At last, but not the least I express my heartfelt thanks to Secretary, Government of Madhya Pradesh, Bhopal Gas Tragedy Relief and Rehabilitation Department and Commissioner-cum-Director, Directorate of Gas Relief and Rehabilitation, Government of Madhya Pradesh, Bhopal for the continuous encouragement for carrying out epidemiological study smoothly. At the end I would humbly place my thanks to all the gas exposees for their continuous support.

Dr. N. Banerjee

Head, NIREH

Former Officer-in-charge.CRS

I. INTRODUCTION

a. Bhopal at a glance

Bhopal, the capital of the state of Madhya Pradesh is situated in the centre of India, at an altitude of 505 meter above sea level (Fig.1). The city is located at longitude 77°12' – 77°40' eastern and latitude 23°07' -23°94' northern. It covers a total area of 284 sq km. The new and old city taken together, the spread of Bhopal is East-West. The population of Bhopal was 672,000 in 1981. The city is administered by the Bhopal Municipal Corporation and for administrative purposes in 1984 the city was divided into 56 wards (Table-1). The density of population was 2355.2/sq.km.¹

In this city of lake and hills, climate is moderate in all seasons. The coldest month is January with mean daily maximum temperature at about 25.7°C, and the mean daily minimum at 10.4°C. After February, the ambient temperature increases steadily till May which is usually the hottest month with mean daily maximum temperature at 40.7°C and mean daily minimum temperature at 26.4°. The city receives its water supply from the upper lake and partly from Kolar dam. The average rain fall was 1234.4 mm for the years 1983-84. The literacy status of the people was 56.77 in 1981.¹

The American Multinational Company, Union Carbide Corporation (UCC) set up a pesticide formulation plant in Bhopal in 1969. The Union Carbide Factory was constructed on a sixty seven acre plot on Berasia Road at the North-West end of Bhopal city. This was meant to mix and package pesticide imported from the USA from late 1977. Union Carbide India Limited (UCIL) started manufacturing Sevin at the Bhopal plant by using imported primary raw materials viz. Alpha Naphthol and Methyl-isocyanate (MIC) manufactured at the Union Carbide Plant in the USA and shipped in stainless steel containers to the Bhopal Factory. However, since early 1980, MIC was being manufactured at Bhopal Plant using the technical know-how and the basic design supplied by the Union Carbide Corporation (UCC), USA. The raw materials used to make MIC were Monomethylamine (MMA) and Phosgene. The latter was produced by reacting Carbon monoxide and chlorine. Carbon monoxide was produced by reaction of petroleum coke with oxygen.¹

b. The Disaster

Ingress of about 512 liters of water in tank No E-610 containing about 42 tons of Methyl Isocyanate, initiated an exothermic reaction overpowering all existing safety systems and resultant products of reaction namely MIC 27-30 tones, Carbon dioxide- 1.25 tones, Ammonia 80- Kg, some amount of Methyl Chloride, Carbon tetrachloride, some alkylamines and cyanide started escaping through 33 meter high vent gas scrubber in to outside cold (10-12°C) atmosphere and continued till the reaction stopped by itself around 3.00AM on 3rd December 1984². And after going through thermal inversion the mixture of toxicants got condensed, settled down and started drifting in to surrounding communities along with the slow moving wind at speed of 10-12.km. per hour. Beside the above, uncertain amount of leftover of the 22 chemicals procured over periods of 15 year for making Sevin (cited above) too were lying unattended in

factory premises. Were likely to cause the environmental damage and damage to health of exposed human population and flora and fauna.

Toxic gas mixture spread rapidly into J. P. Nagar, Kazi camp, Chhola Road, Chandbad, New Kabad Khana, Sindhi Colony and Railway Colony. Most people were at home when the accident occurred. This mid night accident left people awestruck, confused, and panicked and these mental states led them to leave comparatively safety of their houses and running in to dark and often poorly lit streets, moving in different directions. Many a time, instead of running towards safe gas-free zones, they inadvertently walked into more concentrated toxic Gas pockets.

c. Immediate Mortalities and Morbidities

People first noticed irritation of eyes, rapidly developing into intense swelling and burning sensation and inability to keep them open. Simultaneously, people were violently coughing, unable to breathe and feeling suffocated. Many of the exposed persons experienced the smell and sensation like that of burning chilies in eyes. A large number of deaths occurred instantly at home, in streets and hospitals over the next 72 hours. Estimates placed the number of dead persons around 2,000 and dead cattle around 1,000.³

d. Autopsy Findings:

Autopsy studies were carried out by the Medico-Legal Institute and the Department of Pathology from the third day onwards i.e. about 72 hours. The ICMR team helped in carrying out autopsies from December 13-21, 1984 and subsequently the histopathological studies. Initial autopsy studies during the first four weeks revealed a characteristic “cherry red discoloration” of lung, the primary target organ alongside massive pulmonary edema, emphysema and haemorrhage, generalized visceral congestion, cerebral edema, ring haemorrhages and anoxic brain damage. Thus, most deaths had occurred due to asphyxia as a result of acute lung injury, chemical pneumonia or acute respiratory distress syndrome. Extensive pulmonary edema and exudative lesions were observed during subsequent autopsy studies carried out on victims succumbing one to four months post-exposure. Later studies from four months to one year and beyond revealed diffuse interstitial pulmonary fibrosis (DIPF)⁴

Besides these immediate losses of life a much larger number suffered with respiratory, ophthalmic, gastrointestinal and musculo-skeletal complaints.

Acute phase morbidities arbitrarily covered period of 0-1 month post exposure to toxic gas leak. Kamat et al., studied 78 patients during acute phase and found that 79% had respiratory symptoms and 74% had ophthalmic symptoms.⁵ Mishra et al., reported that during the acute phase of the 544 patients examined in OPD 99% suffered with breathlessness, 95% with cough, 46% had choking and irritation, 25% had chest pain, 21% were listless, 16% suffered with hypersomnolence, 7% were brought in coma, 92% suffered with loss of appetite 52% had nausea and vomiting, 82 % had rhonchi and crepts 80% had tachypnoea, 54% had tachycardia and 2% had fever.⁶ Kamat et al., found that 78% showed restrictive pulmonary impairment with reversible airflow obstruction, in 24% reduced oxygen uptake on exercise among 55% and raised levels of carboxyhaemoglobin, and methaemoglobin.⁷ Among 500 Chest radiographs of

patients taken within 72 hours of gas disaster, 98% showed abnormalities of interstitial and alveolar lesions and destructive lesions of pre-existing lung diseases.⁸ Hematological profile of 237 cases at 2 weeks post exposure revealed haemoglobin level of 14%, increased polymorphonuclear cells among 35%, lymphocytosis among 52%, 19% had eosinophilia in excess of 20%. At the time of the gas leak common complaints related to eyes were foreign body sensation, burning, excessive lacrimation, photophobia and blurring of the vision. On detail examination 60-70% had conjunctival and circumcorneal congestion with relatively little edema. A fair number of cases had superficial corneal ulcers, mainly involving central zone and interpalpebral fissure.⁹

e. Aftermath of disaster.

i. Acute phase

Arbitrarily relates to the first month of post exposure period. Men and women of all age groups flooded the hospitals within few hours of the gas disaster. Over 2000 hospital beds belonging to the Government and public sector were commissioned. Improvised camp hospitals were also set up for treating never ending stream of casualties.

Symptoms related to the respiratory tract consisted of choking, difficulty in breathing, pain in the chest and severe cough. Eye complaints were foreign body sensation, burning, excessive lacrimation, photophobia, intense pain and blurring of vision. With the prompt and appropriate treatment, majority of the patients responded well and became symptom free within few days.

ii. Sub-acute phase

Sub-acute phase was characterized by persistent morbidities among survivors of the acute phase. This period arbitrarily relates to 1-3 months post exposure.

iii. Chronic Phase

Chronic phase consisted of subject seeking medical assistance for the persistent symptoms or new symptoms related with respiratory, eye, gastrointestinal, neurological, muscular and mental health illnesses, disturbed sleep, severe loss of working capacity. This continued even after four years of gas disaster.

In vast majority of the exposed subjects, irrespective of the severity of exposure, symptoms of cough with or without expectoration, wheezing, chest pain, breathlessness; severe muscle weakness, body aches, epigastric pain, loss of appetite, visual disturbances, disturbed sleep, and severe loss of work capacity persisted even after 3 to 4 months after the disaster.

f. Centre for Rehabilitation Studies (CRS)

From April 1995, Centre for Rehabilitation Studies of Bhopal Gas Tragedy Relief & Rehabilitation Department, Government of Madhya Pradesh, reinitiated the study titled "Long-term Epidemiological Study" on the similar guidelines.

II. AIMS AND OBJECTIVES

The long term epidemiological study on health effects of the toxic gas exposure through community health clinic was started in mid January 1985. As the size of the exposed/affected population was very large, the statistical design of the studies required to register sufficient number of persons from the exposed areas to document the immediate and the long term effects of the toxic gas inhalation. For comparison a matching cohort from the unexposed/unaffected areas was also planned. Keeping these in view, the objectives of the Long term Epidemiological Studies were:-

- i) To register cohorts in the affected and unaffected (control) areas of Bhopal.
- ii) To collect baseline data on socio-economic and demographic profiles and to study changes over a period of time in context of the exposure to the toxic gas.
- iii) To observe mortality and morbidity in the registered cohorts of population and to establish a relationship with the grades of exposure of the affected population.
- iv) To identify sub-cohorts for in-depth epidemiological studies. Detailed information on demographic, socio-economic status and the base line data on the effects of gas exposure were recorded for preparing a comprehensive register of persons for undertaking detailed clinical and other studies.
- v) To establish linkages between various studies and with the studies on the affected population outside the cohort.

For this purpose, a detailed health survey proforma was structured and the questionnaires (Annexure-I) were administered to the individuals by specially trained field workers. The objectives of the study were reviewed from time to time for mid-course corrections/modifications including changes in the periodicity of data collection.

Following modifications were done in 1987 :

- i) To study the changes in socio-economic and demographic patterns of the study area through annual survey.
- ii) To study mortality, socio-economic and demographic events occurring in the sample.
- iii) To study point prevalence morbidity in the sample cohort along with six monthly morbidity survey.
- iv) To establish linkage with clinical studies initiated by ICMR.

Again, 1989 onwards the study was continued on total cohort.

III. Methodology

a. The Toxic Gas Exposed Areas and Population

From the 1971-81 base, the population of Bhopal was estimated and after allowing an annual growth rate of 7.4% on December 1984 it came to 832904 and 894538 in 1985. This population was living in 56 wards. On the basis of symptomatology revealed by Bhopal population following exposure, these 56 wards were further divided into 36 gas affected and 20 not affected wards (Table -1). On the above basis Municipal Corporation of Bhopal, prepared a map outlining gas affected and non affected wards (Figure-1).

b. Study Design

The objective of the epidemiological study was to determine both short-term and long-term health effects of the gas on the exposed population. Keeping this as the aim, a cohort approach was planned. Initially, as there was no sampling frame available on the list of exposed persons or the list of households living in the exposed area, a “cluster sample” approach was adopted for the study.

The study was planned initially to include 20,000 persons from each of the three exposed areas and an equal number from the control area. The figures presented in Table 3 are the number of persons enumerated in the 1985 survey.

For study purposes, the wards were further sub-classified into localities. The localities were selected at random and were included as clusters in the study. The severely exposed area included four localities, the moderately exposed area included six localities and the mildly exposed area included three localities. The unexposed area included three localities (Figure-1, Table-3).

A major part of the exposed area close to UCIL, was slum locality with no house numbering and no information was available on the residents of these areas. Initially, during January 1985, “a house-listing operation” was carried out to list the households and also to provide an “identification number” for the purpose of long-term follow-up. A door-to-door survey was

carried out in the selected localities to list the households, and a tin plate with house number was affixed on each house. Along with this, a family folder was prepared which included the identification number of the household and the list of members residing in the household, with specific identification number for each individual. This folder was provided to each household for future reference and to ensure better linkages of data collected on a long-term basis through various projects. Each of the selected exposed and control areas were covered in this operation. This activity was completed by March 1985. All the persons listed in the baseline survey formed the cohort for the long-term study.

In the early post-exposure period, it was planned to collect data on morbidity and mortality on a fortnightly basis. The fortnightly survey was initiated from April 1985.

A detailed epidemiological study was carried out during August-October 1985 to record the base line data on demographic, socio-economic characteristics of persons and the immediate morbidity and mortality in the three Gas exposed areas and in control area. The details of the number of persons enumerated in the study in the exposed and unexposed areas are given in Table-3.

Table 3
Distribution of Families and their Population (1985)
According to Area and Locality

Areas	Municipal Ward Number	Locality Number	Name of the Locality Aug-Oct 85	Families Covered Aug-Oct85	Population Covered	Average Family Size
Severely Affected	13	01	J.P.Nagar	1724	8060	4.67
	13,20	02	Kazi Camp	1647	7829	4.75
	20	07	KanchiChhola	1147	4623	4.03

	36	16	Habibganj	1112	4814	4.3
Total	Three	Three		3649	15931	4.36

During the period (August to October 1985), the collection of fortnightly morbidity and mortality data was discontinued because of detailed time bound base line survey. The system of fortnightly surveys was restarted from November 1985 and continued up to December 1986.

During January to March 1987, all households included in the survey were revisited to update the cohort registered to exclude the persons who had moved out and also to check on the deaths and births which occurred in the family after the survey carried out during August-October 1985.

The Project Advisory Committee took a decision to initiate six monthly surveys instead of fortnightly surveys, from May 1987. These surveys were planned on a sub sample from the main sample. The localities included in the severely affected areas were 1 and 7; in moderate 3, 5, 9 in mild 11, 13 and in the control area 14 and 16.

The updating of the cohort was carried out on annual basis in the six monthly surveys during November to May. This procedure was continued for four six monthly surveys i.e. up to November 1988. A further modification was made from November 1988 to include the total cohort instead of sub sample from the main cohort. The collection of information on morbidity and mortality and annual updating of cohort is being continued till date.

c. Operational Plan

The study team included both the medical and non-medical personnel. The non-medical personnel (Research Assistants – RA) were involved in the survey work of visiting each household for collection of information on vital events, morbidity and mortality and the medical personnel (Assistant Research Officers – ARO) for quality control purposes as well as for recording the cause of death.

One RA was allotted to cover one area. It was planned that each RA would visit his/her area and enquire and record all the information regarding morbidity, mortality and on pregnancy within the registered cohort since last visit. A detailed Proforma (Annexure- I) for recording the information on the immediate morbidity and mortality in the exposed and unexposed areas was developed. Information was collected from the “Head” or from “senior member” of the household. If any member was ill, his/her name, identification number and details of the morbidity and other information regarding hospitalization etc. were recorded. The morbidity data was collected on the basis of symptoms. A list of 40 symptoms (see Annexure-I) was provided to RA for recording the morbidity. Similarly, if any death had occurred in the household, the date, month, year of death along with cause of death were recorded. The International Classification of Diseases was followed for coding the cause of death. All these families were followed up by the ARO to verify and confirm the cause of death. A built-in mechanism was followed for checking the information generated by the RA.

The RA submitted, completed proforma on weekly basis to the statistical unit for scrutiny. The data received at the statistical unit were being scrutinized within a week. All the discrepancies observed were listed and the Proforma needing any correction were kept separately. A weekly meeting was arranged with the Principal Investigator along with RAs, AROs, computer and statistical staff to discuss the problems, if any, encountered in the study. All the proformas with any discrepancies were discussed and necessary corrections if needed were

carried out or the proformas requiring corrections at field level were returned. The data were manually analyzed and report was prepared and presented.

In addition to the “Statistical Unit”, a separate unit named “Data Base Information System” was started. The Data Processing Unit in addition to providing support to epidemiological study was the main source for providing appropriate sample for other studies and for preparation of data files of these studies for analysis along with report preparations.

Six community health clinics were set up in the study area, which were managed by the AROs. These clinics were situated in both affected and in the unaffected areas. Five clinics were established in exposed and one in unexposed area. The objectives of these clinics were:

- i) To develop rapport with the persons in the selected area.
- ii) To provide primary health care including treatment of common ailments to the registered cohort and to maintain records.
- iii) To refer cases for specialized investigations and treatment to referral hospitals.
- iv) To collect and maintain additional information on morbidity pattern through the clinics.
- v) To assist various investigating teams in identifying the requirements of exposed and unexposed persons.
- vi) To assist in the maintenance of cohort for long-term study.
- vii) To monitor health problems on the registered cohort.

d. Validation of the data

The Assistant Research Officer (Med.) was to check on 100% of the work carried out by RA's in their respective areas. The families with morbidity were visited by Assistant Research Officer (Med.) to verify the recording of the RA for the accuracy of morbidity data. All the families where death was recorded during the visit of RA were followed up by ARO to find out the cause of death. The International Classification of Disease was followed for coding the cause of death. 10% of the 'no morbid' families reported by the Research Assistant was also to be verified by the Assistant Research Officer (Med.)

1. At the field level

- a) The medical personnel verified hundred percent of the work carried out by RAs in the respective area.
- b) The families with morbidity were visited by the medical personnel to verify the recording of the RA for the accuracy of morbidity data.
- c) 10% of the families given as no morbid were also verified.
- d) Field work by Principal Investigator
- e) All the families where deaths and births and morbidity were reported by the RA during their field visit was 100 percent verified and the cause of death was noted down by the medical personnel following the code of International Classification of Disease.

2. At the pre-analysis level

- a) Once the data were collected from the field it was submitted in the statistical division of the institute.
- b) Here the data was thoroughly scrutinized for any discrepancy, lack of information, consistency.
- c) If there was any discrepancy the data was returned to the field for necessary correction.
- d) After the scrutiny the data was manually analyzed and further sent to the computer section.

3. At analysis level

- a) After the data was received at computer section it was entered into computer for analysis.
 - b) The data was also rechecked for any duplication of information.
 - c) After going through this procedure the data was analyzed
- The operational aspect and validation of the project continues to be carried out by 90% of the same staff which was present at the time of initiation of the project.

HIGHLIGHTS

Summary, Recommendations & Conclusions of Technical Report on Population Based Long Term, Epidemiological Studies 1985-94

1. It was concluded that the Bhopal Gas Disaster was the worst industrial accident of the world occurred on the night of 2nd& 3rd December 1984 in Bhopal.
2. It was estimated that of the total population of Bhopal over 800,000 and about 500,000 were exposed to the toxic gases, out of the total population nearly 160,000 lac people present within a radius of 3 Km. from the factory, were exposed presumably to higher concentration of gas and also perhaps for a longer period of time.
3. In the campus the number of deaths occurred and 85% of these deaths, occurred in the first three days.
4. Of the survivor populations large number suffered from multi-system morbidities, particularly the respiratory, ophthalmic and gastrointestinal systems.
5. With passage of time, the prevalence rates and intensity of clinical signs and symptoms gradually decreased. However, even after 5 years of the toxic gas exposure several thousand attended the hospital and clinics daily for seeking medical relief.
6. The Technical Report opined that the mortality and morbidity caused by the toxic gas(es) inhalation was a onetime acute injury to the respiratory track and the ophthalmic system and often healed with resolution of necrosis and fibrosis, but did not lead to progressive pulmonary or ophthalmic diseases leading to blindness.
7. People with pre-existing lung diseases (presumed at least 5% in any population) or smokers, after gas exposure would have suffered more than those who were healthy before the exposure.

Expert Epidemiological Group

During 25 years of its operation, the study gathered huge amount of data and it becomes a very difficult task to review data of about 44 visits visually and intellectually through single table. Hence it was decided to take the opinion of Expert Epidemiological Group which after deliberations advised to analyze the data under the following guidelines.

1. Analysis to be undertaken for 1986, 1991 and 1996 onwards on yearly basis. Reduction in morbidity over the time is to be highlighted in four areas in addition to present morbidity rates.
2. Comparison of age and sex distribution at aforesaid different points of follow-up to be attempted across all areas.
3. The morbidity pattern to be presented for system specific morbidity.
4. Morbidity analysis to be considered with present age of cohort.
5. The symptom wise analysis to be undertaken based on GI symptoms.
6. The study undertaken after 1986 to compare with 0-4 years of 1986, ten years hence to compare with 10-14 of 1986 and like-wise for other age groups.
7. The analysis also should take into consideration, migration of population providing the details of migration in the appendix.
8. Those individuals who were not symptomatic/not morbid at the time of event but became morbid at some point of time in later years to be explored for analysis.
9. Age specific mortality rate to be considered for the analysis taking into account the age at death.
10. Specific mortality analysis by taking into account age at death.
11. The consistent color quotes to be adopted in representing the mild, moderate and severe area data in graphs in all parts of the report.
12. The characteristics of the sample which was available for follow-up throughout during 1986-91 and 1996-2010 to be documented and compared with the total samples. Also the morbidity pattern of this sample to be analyzed separately.

e. Over view of the presentation

Data of the study has been presented under four headings namely cohort progression, demographic and socio-economic profile, mortality including pregnancy outcomes and morbidity profile.

i. Cohort progression-1985-2010

To recapitulate it is being mentioned that a cohort of 80,021 in affected and 15,931 in control area was assembled in 1985. Over the years since 1985 this cohort experienced population loss following various factors like population movement.

ii. Demographic and socio-economic profile

To understand the socio-economic variables like religion, education, occupation, smoking, use of alcohol, tobacco chewing habits, type of houses, nature of family, smoke outlet facilities, cattle-shed, latrine, kitchen, disposal of animal and human excreta, protection of food and dietary habits etc. were being collected. All these factors directly or indirectly presumed to have impact on morbidity pattern. Main socio-demographic variables for the year 1996, 2006 and 2010 have been presented.

iii. Mortality

The mortality rates for each calendar year from 1996 to 2010 are presented by age wise manner.

iv. Pregnancy outcome

The pregnancies and their outcome for calendar year up to 2010 are also presented. In Table -30.

v. Morbidity

As mentioned earlier, only the persons registered in the baseline cohort were included for analyzing the data on morbidity. The analysis was carried out as cross-sectional morbidity rates for the persons enumerated at each of the follow-up points of time. All the households contacted and the persons residing in the households were included for estimating the morbidity rates. The numerator included those who were morbid on the day of survey and the denominator included those who were enumerated and available as residents in the household on the day of survey. The details of morbidity by age and sex for each of the morbidity are presented in this report.

IV. OBSERVATIONS

At the outset it is very important to note that this long-term follow-up study is one of the rarest studies which continued over a long span of the time and still continuing till date, almost 27 years after the disaster. During this period, the study went through three administrative changes i.e. initially it was conducted through a project supervised by Indian Council of Medical Research till December 1994, then it was continued under Center for Rehabilitation Studies under Department of Bhopal Gas Tragedy and Rehabilitation Govt. of M.P. till 2011 and since then it again came to National Institute for Research in Environmental Health under Indian Council of Medical Research. It is natural for such long-term study to lose some part of the cohort due to various reasons like migration, deaths, non response etc.

Before making observations on collected data it would be pertinent to recapitulate the findings noted in earlier technical report of the project for the period 1985-1994. Observations mentioned below which have been taken verbatim from chapter VI: summary, recommendations and conclusions.¹⁰

- i) Soon after the gas disaster, 36 wards having population of 521,262 (62.6%) were found to be exposed and affected, while 20 wards with a population of 311,642 (37.4%) were found to be unaffected by the gas.

- ii) On the basis of average death rates in the exposed/affected areas, the latter were categorized into: severely exposed/affected average death rate of 22/1000, moderately exposed/affected area average death rate of 1.33/1000, and mildly exposed/affected with average death rate of 0.20/1000. The unexposed/unaffected area was categorized as the control area. In the text, these areas are often referred to simply as severe, moderate, mild and control area.
- iii) Age and sex distribution of the population of “affected” as well as “control” areas were almost similar comparable to national population pyramid.
- iv) A noteworthy feature was that the “death rates” were higher in the “exposed areas”, than in the “control areas” throughout the ten years period of observations.
- v) The “Gas exposure” particularly in the severely affected area showed higher mortality in the initial years, which gradually declined and nearly touched “local” or “national levels”. Deaths in the exposed area were mainly due to respiratory disorders throughout the period of observations. Death rates were higher in the age group of 45 years and above.
- vi) Another notable feature was the “pregnancy rate”, which is generally associated with disasters in general. The rate was high till 1986 – 87 and gradually declined over a period of time. Likewise, by 1989 the “abortion rate” in the affected areas, which was initially 12%, declined to about 7.5%, as against 1.4% in the control area.
- vii) General morbidity as well as that traceable to respiratory or ophthalmic morbidity, based on the symptomatology reported by the patients or the responsible family members, was observed to be consistently higher in affected areas as compared with the control areas. The “immediate” morbidity was about 95-97% for both pulmonary and ophthalmic involvement.

a. Cohort

In 1985 when study was conceived, acute effect of toxic gas release were studied on a cohort of 80,021(26,382, 34,964 and 18,675 from severely, moderately and mildly affected localities) along with a control population of 15,931. However, when study was actually started in 1986, a population of 19,260, 28,261 and 15,185 from severely, moderately and mildly affected area respectively and 13,526 from control area could be contacted for study. Of the actually available cohort of 62,706 from affected area and 13,526 from control area in 1986, only 5,658, 6,533 and 4,669 from severely, moderately and mildly affected area respectively (total-16,860) and 5,741 from control area were actually available for study in 2010.

Table-4
AGE WISE DISTRIBUTION OF COHORT(YEAR- 1986 -2010)

SEVERE AREA

Years	0-4	%	05-14.	%	15-44	%	45-64	%	65+	%	Total

2010					3182	55.42	2000	34.84	559	9.74	5741

For the details see table no 12 to 15 in Annexure

Table No. 4 gives the consolidated data on age wise distribution of cohort for period 1986 to 2010 for three affected areas and control area. Over the years as study progressed there was a natural shift in age groups with passage of time. By 1999 only three age groups i.e. 15-44, 45-64 and 65+ remained available for the follow-up in affected as well as control area, The details of which are presented in tables 12 to 15.

From the Table-4 and figure 2 it can be deduced that proportionate distribution of the population among the available age groups in all the areas fluctuates within the narrow range.

Figure : 2. Age wise distribution of cohort (1986-2010)

a-i. Sex wise distribution of cohort

Initial (1985) and mid- decadal analysis of the cohort in 2006 revealed that age and sex distribution of the affected and control population participated was similar from the angle of proportion of population in affected and control area in both sex in terms of percentage at three different points of times namely 1985, 2006, 2010. The details of the same have been represented in table 16 to 19 in Annexure.

Table 5
Sex wise distribution of the cohort Population over the years

	Severe	Moderate	Mild	control
Year	n/ (M%:F%)	n/ (M%:F%)	n/ (M%:F%)	n/ (M%:F%)
1985	26382/ (53.09:46.91)	34964/ (52.75:47.27)	18675/ (52.02:47.98)	15931/ (53.83:46.18)
2006	4961/ 49.9%:50.10%	5834/ 50.87:49.13%	4814/ 48.87%:51.13%	5338 51.70%:48.30%
2010	5658/ 49.78%:50.22%	6533/ 50.16%:49.84%	4669/ 49.19%:50.8%	5741/ 51.69%:48.31%

For the details see table no 16 to 19 in Annexure, n denotes total Numbers ,
M = Male, F= Female

b. Socio-Economic Profile

Religion:- During 1985, 73.92% Hindu Community represented in severely affected area whereas in 2010 only 47.50% have participated. Similarly in moderate area instead of 35.05% they have increased to 44.14% whereas in mild area from 40.08% it has come to 36.57%

Muslim Community represented 25.49% during 1985 whereas in 2010 they are in 52.15 percent in severely affected area. In moderate area, their participation was reduced from 62.5% to 52.85%. In mild area from 58.20% to 62.46% In control area it has dropped from 7.55% to 4.22%.

There is a cross reduction in the participation of other religions namely Christian, Sikh and others uniformly in affected and control area.

- i. Education status: it was found that over the period of 1985-2010 educational status has increased in affected as well as control area. Proportion of illiterates has gone down (example in severe area from 60.85% to 22.71%) in all areas. Proportionately literacy has increased up to secondary level, while there is little change at collegiate and technical education level (Table no.- 20,20A).
- ii. Socio-economic class and per capita income: it has been observed that between 1985 and 2010 there has been very significant improvement in per capita income in affected as well as control area 0.04% to 59.54%, in severe area, control area (Table no.-20 and 20A).
- iii. Housing: In the year 1985 during base line survey it was observed that 71.79% in the severely exposed area have been living in Kachha House, while in year 2010 this proportion came down to 11.50%. Same pattern was observed in moderately and mildly exposed area as well. However, in control area in 1985 only 11.41% were living in pucca houses, this proportion increased to 35.19% in 2010.

- IV. Tobacco Smoking: The study also tried to find out about the use of tobacco smoking, as it may be imparting confounding effect to respiratory morbidities and to cancers. It was found that over the period of 1985-2010 smoking was seen prevalent as 9.90 to 13.01% in affected area. The smoking habits appear to be increasing in affected area except in the severe area and the same is true for control area where it was increased from 6.62 to 13.98%.(Table no. 21) These finding are in agreement with the observations of the "Population Based Cancer Registry", which identified the higher rate of cancer in MIC affected area, was due to higher proportion of population consuming tobacco rather than due to the effect of MIC exposure per se.¹¹

c. Mortalities

i. Annual Mortality

Mortality during post exposure acute phase (4th -31st December 1984) was very high i.e. 12.57/1000 for males and 11.6/1000 for females in severely affected area. The corresponding figures for moderate were 0.71 and 0.56 and for mild 0.1 and 0.22. It was in sharp contrast to that observed in control area (0.35 and 0.41 respectively).¹²

During 1985 to 1993 the annual mortality figures in severe area ranged between 7.4 -3.4 for males and 7.8-1.6 for females. For moderate area these figures ranged between 6.5-3.2 for males and 5.4-2.6 for females and in mild area 6.1-2.5 and 4.6-2.4 for females. In control area these figures ranged 3.9 and 1.9 in males and 4.2 and 1.9 in females. Generally a decreasing trend in death rate has been observed in all the areas. However, the death rates till 1993 and later were observed to be higher in affected area in comparison to control.¹²

Death rates observed between 1996 to 2010 bring out the fact that crude death rates were lower than the national crude death rates (2002 to 2009) (Table No. 6). However, death rates observed in 2010 reveal that except in severely affected area (5.48/1000) death rates were higher in mildly (8.25/1000), moderately (8.11/1000) and control area (6.1/1000) (Table 22). The reason being the higher ages representing more in the cohort follow-up and the respective age related issues irrespective of whether belong the affected area or control area. In fact during the year 2010, 90.91/1000 age specific mortality rate have been recorded in 85+ age group (Table. 27).

ii. Age specific Mortality

The mortality rates were very high during the acute phase. The mortality rate calculated for the period of 3rd to 6th December 1984 were 21.98 in severe, 1.33 in moderate and 0.29/1000 in mildly affected area. For period 4th -31st December 1984 these were 12.57/1000 for males and 11.6/1000 for females in severely affected area. Mortality rates showed a decreasing trend with passage of time throughout the study. In present study (1996-2010), mortality rates most of the times (2002-2009) less than the national crude death rate. Death rates observed between 2002-2009 bring out the fact that Mortality in all age groups has remained under national urban death rate for respective age groups in this respective year, except occasional and slight increase as mentioned in table no.6 and figure. no. 3.

Figure : 3. Age Specific Mortality Rate during 2002- 2009

iii. Primary Cause of Death

The information on causes of death was included since 1986: cause of death analysis is based on 3978 death records collected during 1986-2010. Between the periods of 1986 to 2010 most common cause of death was observed to be respiratory in affected area followed by digestive and cerebro-vascular disorders. In control area too respiratory disorders were the most common cause of death though with lesser frequency, followed by digestive disorders and fever (Table no 22-26).

Figure : 4. Primary Cause of Death during 1986-2010.

Cont.... Figure : 4.

iv. pregnancy outcome

During the initial survey carried out in Feb-March 1985, a separate “card” was adopted to collect the information on outcome of pregnancy. The pregnancy status of all married women in the age group 15-49 years along with the pregnancy outcome was also recorded during survey in August-October, 1985. Since January-December, 1986 a different format was introduced to collect detailed information on pregnancies through fortnightly visits of the families. From the year 1987 onward, these data were collected through six monthly follow-up of the families. It can be seen that immediately after the disaster, in the severely affected area, the abortion rate was 523 per 1000 (Table-36 in annexure Technical Report, 1985-1994). The abortion rate showed a decreasing trend from severely to mildly affected area. In the subsequent years there was a declining trend in the abortion rate in all the exposed area. In the control area abortion rate for December 1984 was 83 per 1000. No clear pattern was observed in the exposed area with regard to still birth rates.¹⁸ From the year 1996 onward, these data were collected through six monthly follow-up of the families. The data for the year 1996-2010 is presented in Table 30 in annexure, however due to scarcity of data no clear pattern could be interpreted.

d. Morbidities

As mentioned earlier during the surveys information on morbidities were collected through a proforma enquiring about the forty symptoms. These symptoms were further re-grouped under the following systems:

Systems (morbidities) with their codes (Annexure –I):

- | | | |
|---------------------------|---|----------------------------|
| 1. General Morbidities | - | Over all morbidities |
| 2. Respiratory | - | 1, 2, 3, 4, 5, 28 |
| 2. Ophthalmic | - | 19, 20 |
| 3. Gastrointestinal Tract | - | 16, 17, 18, 22, 25, 31, 39 |
| 4. Skin | - | 23 |

i. Acute Stage Morbidities

During acute stage in all the three exposed areas 96-99% had both eyes and lung symptoms, while 74% suffered with gastrointestinal symptoms in severely exposed area, whereas in moderate and mild area it was 48% and 14% respectively. Morbidity related to skin was among 1.2% in exposed area. The control area had very low morbidity during the same period (Table 7-11).

ii. General morbidities

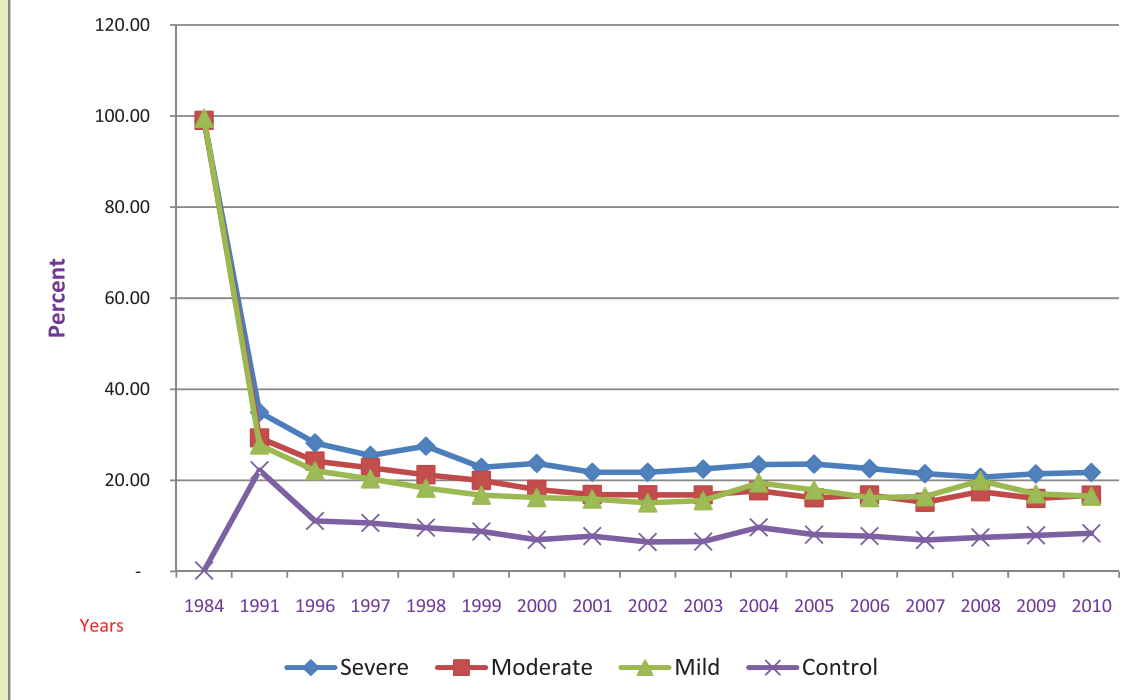

Immediately after the disaster the morbidities were very high to the extent of 98.99%, 99.05% and 99.54% in severely, moderately and mildly affected area. Morbidity rate in all areas indicated three distinct trends indicating a low rate up to the survey during May 1988 to November 1988 later an increased trend up to survey in November 1990 to May 1991 and afterward a decrease. By six years post disaster in 1991 these morbidities came down to 34.94%, 25.88% and 27.77% in the same areas and showed further decline to 28.20%, 24.23% and 22.11% in respectively. There was further decline in all the areas. By 2001 general morbidities came down to 21.76%, 16.88% and 15.90% in severely moderately and mildly affected area. Since 2006, general morbidities have been seen fluctuating between 22.58% to 20.66% in severely affected area, 16.02% to 17.49% in moderately affected area and 16.22% to 19.93% in mildly affected area. However, these were higher than morbidities seen in control area which continued to fluctuate between 6.54% to 10.63% since 1997.

2010	5658	978	17.29	6533	641	9.81	4669	608	13.02	5741	147	2.56

For details see Table no. 32 in annexure

During acute stage 96.87% suffered with respiratory morbidities. In the severe area, the morbidity specific to lung for males was higher in all the follow-up periods compared to other two exposed and control area. Up to November 1988, there was no pattern in severe area, while in May 1991 there was an increase and later on a fall was noticed. The Respiratory morbidities came down from 96.87% in 1984 to 20.41%, 16.99%, and 16.46 % in severely, moderately, mildly affected area in comparison to 4.37% in control area. Since 1997, these morbidity rates are seen fluctuating between 20.31%-15.42% in severely, 15.43%-9.63% in moderately 16.41%-13.02% in mildly affected area. These respiratory morbidity rates remained high in all affected areas in comparison to control area (0.06%-4.37%) throughout 1984-2010.

iv. Ophthalmic Morbidities

During acute phase in 1984 affected area experienced 98.50%, 98.08% and 99.00% ophthalmic morbidities in severely, moderately and mildly affected area respectively in comparison to 0.07% experience by control area population. By 1996, ophthalmic morbidity rate came down to 16.60%, 12.41% and 14.98% in the same areas in comparison to 4.31% observed in control area during the same period. These rates declined further and have been seen fluctuating between 11.46%-15.85% in severely affected area, between 9.00%-11.07% in moderately affected area and 13.99%-17.89% in mildly affected area in comparison to 2.84%-3.43% in control area during 2005-2010.

For details see Table no. 33 in annexure

Fig:7. Ophthalmic Morbidities (1984 - 2010)

v. Gastrointestinal morbidities

During acute phase in 1984, 73.53%, 26.36% and 15% suffered with gastrointestinal morbidities in severely moderately and mildly affected areas in comparison to 0.01% in control area. However, within five years by 1991, these morbidity rates fell down to 7.99%, 6.52% and 5.88% in the same areas in comparison to increased Gastrointestinal Morbidity rate of 5.80% in control area. Later since 1996 to till date, Gastrointestinal morbidity rates have been seen fluctuating 6.48%-4.49%, 5.21%-3.29% and 4.56%-13.61% in severely, moderately and mildly affected area in comparison to 1.24%-2.77% in control area. The peaks of rise in morbidity rates in mild area were further analyzed and it was found that these peaks noticed in mild area were due to excessive reporting of symptom like abdominal pain (Symptom no 17) and gastritis (Symptom no 31).(Table no. 35-38 in annexure)

For details see Table no. 34 in annexure

vi. Skin morbidities

Skin morbidities were observed in less than 1.82% in all area during acute phase observed in 1984, during acute phase no morbidity was reported in control area. Morbidity rates were marginally higher in all areas including control in 1996 which later except one peak in 1998 (2.24%) in severe area remained at the level or less than 1.63% in severe area and less than 1% in all areas including control. Since 2007 to till date even in severely affected area skin morbidity rate remained under 1%.

Table 11

For details see Table no. 39 in annexure

vii. Age specific Morbidities

In all affected areas morbidities increased with increase in age. As age is a confounding factor for increase in morbidities. And the same has been observed in control area as well (Table no.40-43. in annexure)

V. DISCUSSION

a. The Backdrop

The Bhopal Gas Disaster (BGD) which occurred on the 2nd/3rd December, 1984 as a result of escape of 40 tons of a highly toxic liquid in a gaseous form along with other reaction products led to unprecedented damage to environment, and loss to lives both of animals (1000) and human beings (2000) within first 72 hours.

Besides, the immediate loss to human lives as stated above it was believed that the toxicants released during the accident may have long-term effect on human health and its different physiological subsystems like respiratory, ophthalmic gastrointestinal, skin, mental health, growth and development including dentition. It was also feared that the toxicants may have effect on fertility pattern, pregnancy and pregnancy outcome and even on the progeny of the gas victims in form of congenital malformation. Besides this toxicants may lead to damage at microcellular, cellular level thus leading to emergence of cancers among the affected population.

Looking at above, Indian Council of Medical Research in association with Institutes of national prominence and research scientists of international and national repute developed about 20 studies, whose reports have been published from time to time elsewhere.

One of the above mentioned studies was titled as “long term epidemiological studies on the health effects of toxic gas exposure through community health clinics” this study was conceived immediately after the toxic gas leak in 1985 January and was aimed to investigate the epidemiological fallouts of the disaster. This epidemiological study no doubt is one of the rarest and longest running study in India, as it has completed its 25 years of operation in December 2012. The study continued for more than 25 years with same methodology, the way it was planned while it was under Bhopal Gas Disaster Research Center,

The findings of the part one have already been published by Bhopal Gas Disaster Research Center, Gandhi Medical College, Bhopal, M.P. India/ Indian Council of Medical Research, Ansari Nagar, New Delhi-110029. Under “Health effect of the toxic gas leak from the Union Carbide Methyl Isocyanate plant in Bhopal: Technical Report on population based long term epidemiological studies (1985-1994)”

It is pertinent to recall salient features and conclusions drawn in above mentioned report as below:

- a) Soon after the gas disaster, 36 wards having population of 521,262 (62.6%) were found to be exposed and affected, while 20 wards with a population of 311,642 (37.4%) were found to be unaffected by the gas. On the basis of average death rates in the exposed/affected areas, the latter were categorized into: severely exposed/affected area (death rate of 22/1000), moderately exposed/affected area (death rate of 1.33/1000) and mildly exposed/affected area (death rate of 0.20/1000.) The unexposed/unaffected area was categorized as the control area.
- b) This study covered affected as well as control area with a cohort base of 80,021 (26,382, 34,964 and 18,675 in severely, moderately and mildly exposed) in affected area and

15,931 in control area. The study was conducted in 16 localities through 6 community clinics. A concurrent family based population survey initially carried out fortnightly and later six monthly was conducted to find out the patterns of socio-economic, pregnancy outcome, mortality, and morbidity parameters in toxic gas affected population.

- c) Age and sex distribution of the population of “affected” as well as “control” areas were almost similar comparable to national population pyramid.
- d) “Death rates” were higher in the “exposed areas”, than in the “control areas” throughout the ten years period of observations. The severely affected area showed higher mortality in the initial years, which gradually declined and nearly touched “local” or “national levels”. Deaths in the exposed area were mainly due to respiratory disorders throughout the period of observations. Death rates were higher in the age group of 45 years and above.
- e) Another notable feature was the “pregnancy rate”, which is generally associated with disasters in general. The rate was high till 1986-1987 and gradually declined over a period of time. Likewise, by 1989 the “abortion rate” in the affected areas, which was initially 12%, declined to about 7.5%, as against 1.4% in the control area. Such phenomenon has been observed in man-made and even natural disasters.
- f) General morbidity as well as that traceable to respiratory or ophthalmic morbidity, based on the symptomatology reported by the patients or the responsible family members, was observed to be consistently higher in affected areas as compared with the control areas.

With above finding in background the present report covers the period 1996-2010 and for technical content continuity, present report has drawn heavily from the first report mentioned above.

b. Cohort

One of the most challenging tasks in operating a cohort study is to hold the cohort. This study in 1985 started with a cohort of 80,021 in affected (26,382, 34,964 and 18,675 respectively in severely, moderately and mildly affected localities) along with a control population of 15,931. However, of the original above mentioned cohort only 5,658, 6,533 and 4,669 from severely, moderately and mildly affected area respectively (total-16,860) and 5,741 from control area was actually available for study in 2010. In nut shell, study over a period of 25 years suffered a cohort loss of 79% in affected area and 64% in control area. The reasons behind losses are presumably shifting of the population to different places, marriage migration, shifting of young age cohort to older age one and subsequent death of elderly cohort. Now the original cohort in affected area is in the age group exceeding 25 years of their age.

c. Socio economic profile

Study noticed improvement in housing, per capita income and educational status of the population in affected as well in control population.

d. Mortality and related issues

The mortality rates were very high during the acute phase. The mortality rate calculated

for the period of 3rd to 6th December 1984 were 21.98 in severe, 1.33 in moderate and 0.29/1000 in mildly affected area. For period 4th -31st December 1984 these were 12.57/1000 for males and 11.6/1000 for females in severely affected area. Mortality rates showed a decreasing trend with passage of time throughout the study. In present study (1996-2010) mortality rates (2002-2009) are less than the national crude death rate. Death rates observed between 2002-2009 bring out the fact that mortality in all age groups has remained under national urban death rate for respective age groups in respective year, except occasional and slight increase as mentioned in table no.27 and graph no. 3. The study reveals main cause of mortality among gas affected as well control area as respiratory illness.

e. Morbidities

General Morbidities: During acute stage in all the three exposed areas, 98% of persons had both lung and eye symptoms. The gastrointestinal symptoms were observed in 74% in severely exposed area whereas in moderate and mild areas it was 48% and 14% respectively. The morbidity related to skin was about 1-2% in the exposed areas. The morbidity rates in all the areas indicated three distinct trends indicating a low rate up to the survey during May 1988 to November 1988, later an increasing trend up to the survey in November 1990 to May 1991; and afterwards a decrease. The severe area as expected had higher morbidity at all the periods. The morbidity rates in the moderate area were higher than mild area up to May 91. General morbidities showed a decreasing trend, however, always above the control area and since 1999 have been stable under 23%, 20%, 17% and 8% in severely, moderately and mildly affected area and control with occasional peaks in mild and control area till 2010.

Respiratory morbidities: Respiratory morbidities too have followed the similar pattern as seen in case of general morbidities. During acute stage in affected areas 96%-98% people suffered with respiratory morbidities however by end of 7th year post exposure these morbidities came down to 20%, 15% and 16% in severely moderately and mildly affected area and since 1998 have remained below 20 % till 2010.

Ophthalmic morbidities: were seen in 98-99% of the affected population during acute stage. This proportion came down to less than 16% in affected area in 1996 and since 1999 have remained under 20% till 2010.

Gastrointestinal tract morbidities: which started with 74, 26 and 15% during acute stage came down to less than 8% in affected area by 1991 and since then have remained under same level till 2010 with occasional slightly higher peaks in all area. The mild area did show noticeable increase in morbidities ie up to 13% during 2004-2008. The cause of this rise was investigated and it was found that people started complaining excessively about gastritis abdominal pain. This could be possibly due to excessive self medication for pain.

Skin morbidities showed consistent pattern of less than 2% in all areas in all times.

Limitation of the Study: The initial cohort registered population was planned on emergency basis immediately after the disaster in 1984. The study was started with time constraints. The limitations also included study design there were no house numbering or any identification for preparing sampling. In spite of this the areas were demarcated as exposed and unexposed.

There were some effort in shifting of entire population from one area to another which created depletion in the cohort. However, during later period the depletion was not significant as reported in the first technical report of ICMR.

The study was planned as a household study viz. by including only persons living in the households. It should be understood that the deaths of persons without holding the households have not been taken into account. The cohort study was planned to collect information on a longitudinal basis.

Initially, in the acute face, it was planned to collect data every fortnight from all the households and later modifications were made as per the interim recommendations. It may be noted during the period 1993 – 1995 there was no follow-up from any agency, and CRS started follow-up cohort only during 1996.

VI. SUMMARY AND CONCLUSIONS

Multinational Union Carbide factory producing SEVIN, a carbamate pesticide got involved in a disaster due to various operational and safety system failures on the night of 2nd/ 3rd December 1984. It started with ingress of about 500 liters of water in to tank no. E 610 containing 42 tones of Methyl Isocyanate along with some metallic impurities. Ingress of water led to exothermic reaction and thus release of 27-30 tones of Methyl Isocyanate gas along with other products of reaction through 33 meter high vent gas scrubber in to atmosphere at 12°C of temperature and 10-12Km./hrs wind speed in south west direction. Mixture of hot gases got condensed in outside cold air and due to atmospheric inversion phenomenon settled down slowly on the ground. This settled mist or cloud of toxic gas(es) evaporated and spread with low wind velocity,¹⁹ over the densely populated old city situated on comparatively planes surrounded by the high hillocks namely Idgah hills, Shyamla hills and Birla hills on three sides.

The disaster led to death of about 1000 people within 72 hours. Thousands of people symptomatically suffered with irritation of eyes, rapidly developing into intense swelling and burning sensation and inability to keep them open. Simultaneously, people were violently coughing and felt choked, unable to breathe. Many of the exposed persons experienced the smell and sensation like that of burning chilies in eyes. Within twenty-four hours of the single inhalation of the MIC related toxic gas(es), it became clear that this one time exposure is likely to result in multisystem morbidities among the survivors.

Indian Council of Medical Research through its own and along with major research institutions spread all over the country and the academic intellectuals and research scientists of national and international repute planned about twenty two studies to answer this question.

Of the twenty two research projects “The population based long term epidemiological study on health effect of toxic gas exposure through community health clinic was initiated on 1st January 1985 following disaster due to toxic gas leak. The documentation of the part I of the study (1985-1994) is already available in form of a technical report published by Bhopal Gas Disaster Research Center, Gandhi Medical College, Bhopal M.P. India and Indian Council of Medical Research, Ansari Nagar, New Delhi- 110029. The study concluded:

“The mortality and morbidity caused by the toxic gas(es) inhalation was a “one time acute injury” to the respiratory tract and the ophthalmic system and which often healed with resolution or necrosis and fibrosis, but did not lead to progressive ophthalmic disease resulting in blindness. The scars produced after the acute lung injury and their sequel may however, continue to produce recurrent/episodic respiratory illness and possibly disability because of secondary respiratory infection and airway hyper reactivity or fibrosis, emphysema, bronchiectasis etc. for a long time or even the whole life. People with pre-existing lung disease (presumed at least 5% in any population), or smokers, after the gas exposure would have suffered more than those who were healthy before the exposure.”

Present report or part II covers the period of 1996-2010. It concludes:

1. Cohort

Over the period of 25 years (14 years under the present period of reporting) study has suffered a cohort loss of 79% in affected area and 64% in control area.

2. Socio-economic profile

In general the profile has improved on all evaluated parameters.

3. Mortality profile

The mortality rates were very high during the acute phase. The mortality rate calculated for the period of 3rd to 6th December 1984 were 21.98 in severe, 1.33 in moderate and 0.29/1000 in mildly affected area. For period 4th - 31st December 1984 these were 12.57/1000 for males and 11.6/1000 for females in severely affected area. Mortality rates showed a decreasing trend with passage of time throughout the study. In present study (1996-2010) Mortality rates most of the times (2002-2009) are less than the national crude death rate. Age specific mortality rates too are observed to be within national averages, in all areas including control. The study reveals main cause of mortality among gas affected as well control area is respiratory.

4. Morbidity profile

General morbidities since 1999 have been fluctuating under 23%, 20%, 17% and 8% in severely moderately and mildly affected and control area till 2010. Respiratory morbidities since 1998 and ophthalmic morbidities since 1999 have remained under 20%. GIT morbidities came down to 8% affected area by 1991 and since then have remained under same level till 2010. In nut shell it can be said that all the morbidity levels have been fluctuating under 20% since 1999. However, all the morbidities in affected area are found to be higher than the morbidities seen in control area.

Hence, it is recommended that the difference in morbidities in affected area in reference to control area needs to be examined with the help of instituting clinical /clinico-epidemiological studies among those who are either chronically ill or chronically and severely ill, with more clinical orientation using newer clinical diagnostic tools to diagnose the clinical entities among the symptomatic cases identified so far.

VII. RECOMMENDATIONS

The Bhopal MIC toxic gas leak disaster on the night of 2nd/3rd December 1984 led to 1000 death within the following 72 hours. A study titled "The Population Based Long term Epidemiological study on health effect of toxic gas exposure through community health clinics" was initiated on 1st January 1985. This study completed its part I (1985-1994) and through part II study period of 1996-2010 is being reported.

Annual mortality rate came down to level lower than national crude death rate as early as 1985. And since then have remained under national crude death rate till 2010. During acute stage 97% to 99% affected people suffered with respiratory and ophthalmic morbidities, with high abortion rate of 523/1000 and general morbidities (98.99%), respiratory morbidities (98.2%) and gastrointestinal morbidities (74%) in 1984. Since 1999 general morbidities are fluctuating below 23%, respiratory below 20% since 1998, ophthalmic below 20% since 1999 and GIT morbidities under 8% since 1991, however, these symptomatic morbidities are higher than those seen in control area.

Since this study is the only cohort study which has been carried out on gas affected people in last two decades and there is no other health monitoring system with inbuilt research component in practice as on date. Hence it is recommended that newer studies on remaining population of original total gas exposed population of 5,74,000 may be undertaken and extensive follow-up with major focus on clinical disease identification and treatment. The studies should be planned in such a manner so that they can impart guidelines for health service sector to implement treatment measures.

2009					3332	62.14	1607	29.96	425	7.92	5364
2010					3278	57.94	1749	30.91	631	11.15	5658

Table— 12, Gives the details of get distribution at different points of follow-up (1986 – 2010) for Severe area.

The age group 0-4 during 1986 for the area severely affected was 8.04% this age group persisted/represented only during 1986. The age group 5-14 years though it was 29.12% in 1986 it was 0.06% by 1999 and beyond this it was not represented. The group 15-44 years during 1986 was 50.39% subsequently it is representation Increased to 76.42% by 1999. Subsequently there was a gross reduction to the level of 57.94 by 2010. It clearly indicates that in the initial years of the disaster participation of this age group was increasing. After 1999 there was decline may be due to conditions attributable to population going in search of job, some commitment and also their non availability and action of any major morbid condition compelling them to be present at the time of enquiry.

The age group 45-64 during 1986 was 10.64%. Gradually it increased almost 3 folds reaching 30.91% by 2010 indicating their availability for the cohort investigators may be due to morbid condition with a expectation that they get some relief if they make themselves available for the cohort investigator. The age group 65+ at the time of beginning of the cohort during 1986 was 1.78% which gradually increased 10 folds to 11.15% by 2010. The similar reason stated above in respect of 45-64 years can also be referred here.

Table No. 16-19 gives the age sex distribution of the cohort population at different points of follow up for the years 1986, 1991, 1996, 2001, 2006 and 2010 for exposed and control areas. It is observed that the age group 0-4 years was available for the cohort in the percentage range of 6.16 to 8.04 only during 1986. The age group 5-14 years represented 26 to 29% during 1986 subsequently by 1996 it was the 7 to 10%. After 1996 onwards this age group was not available for the cohort. It can be observed from the tables that the age group 15-44 represented in the range of 50.14 to 53.64% except in moderate area where during 1986 it was 5.16%. It can be observed that 9-11% represented age group 45-64 during 1986, among both male and female irrespective of the area. The respective tables for both male and female cohort population in the above mentioned age groups at different point of time indicate statistically comparable percentage/representation. Recognizable and statically acceptable age and sex groups in the respective years validates the observations. It can also be observed from the tables even after 26 years, the same proportion of population in the age group of 15-44 has been maintained and in respect of 44-55 age group there is a 3 fold rise and in respect of 65+ age group 2-5 fold rise in both age and sex distribution.

The comparison of socio economic profile of the population participated the cohort for the years 1985 and 2010 have been represented in Table no 20 and 20a.

Participation of Religion – Hindus		73.92% in 1985, 47.50% in 2010 in	Severely affected area
	35.05%	44.14%	Moderately
	40.85%	36.57%	Mildly
Muslims			Severely affected area
	29.49%	52.15%	Moderately
	62.05%	52.85%	Mildly
	58.20%	62.46%	

In General there is a reduction in the participation of other religions namely Christian and Sikh Community. The same observation holds the respect of control area also.

2010	5658	1229	21.72	6533	1093	16.72	4669	772	16.53	5741	480	8.36

Table 31: Gives the details of general morbidity rates observed during the years 1984 till 2010 in affected 3 areas (severe, moderate and mild) and control area.

The years 1992,93,&94 have not been represented in the Table. The reasons for non consideration have been highlighted in technical report 1985-1994. 3 exposed areas viz. severe, moderate and mild and control areas have been highlighted. It may be noted that the percentage of morbidity during 1984 in the cohort is in the order of 99.05% to 98.99% in exposed areas and it remains only 0.17% in control area.

It may be observed that the morbidity reduced to 34.94 (64.05% reduction) in severe area by 1991 over a span of 5 years. Similarly the morbidity comes down to 28.88% from 99.05% in moderate area (reduction by 73.17% by 1991).

The reduction in morbidity to 27.77% during 1991 from 99.54 of 1984, (77.71%) in mild areas was a notable feature. It may be observed that the reduction in morbidity can be noticed right up to 1998 to the range of 18.292 to 27.50% from mild to severe area demonstrating with the minimum reduction in morbidity was noticed by 1998 i.e. 14 years. The notable observation from Table No7 is the reduction in the morbidity in all the 3 exposed areas is from 98.99% to 16.53% by 2010.

The identified morbidity in 2010 under severely exposed area stands at 21.72% when compare to 16.72 and 16.53 of moderate and mild areas which is significant statistically ($z=7.04, p<0.01$)

In comparison to the morbidity of the control population where the percentage of morbidity recorded is 8.36% there is a significant existing morbidity in all the 3 exposed areas in the range of 16.53 to 21.72%.

The salient points to be understood from table 31 are as follows.

- In the severe area between 1984-97, morbidity declined from 98.99 to 27.50 i.e., by 71.49% which is drastic reduction in the morbidity which is highly significant (statistical validation to be undertaken).

In mild areas the reduction in morbidity rate was 71.77% from 1984-1991 thereby informing in a span of five years, morbidity condition reduced significantly ($\chi^2=3.84, p<0.05, d.f.=1$).

- Recorded morbidity of 22.22% during 1991 from the control area may be a total and co-incidence in attributable to post disaster scenario.
- It may be observed that there is a drastic reduction in the morbidity in all the affected areas from 1984-2010 to 21.72% in severe 16.72% to moderate and 16.53% in mild exposed areas over a period of 26 years. The persistent comparable higher percentage of morbidity observed over 26 years in three affected areas in comparison with the control area needs regular follow-up supported by relevant investigations on the various likely influences which may be existing non symptoms becoming symptomatic over the years or condition of the symptoms under medication being not improved because of certain amount of irreparable damage which might have taken place during the course of time of 26 years. This observation needs an element of doubt to rule out the possibility of concomitant influences/confounding factors which needs to be further investigated scientifically and technically reviewed.

2010												

It may be observed that the morbidity which was 96.87% during 1984 drastically dropped to 20.31% by 1998 which is highly significant.

Table – 32 gives the distribution of pulmonary/lung morbidity rates observed during the years 1984-2010. It may be noted in each category for each year the details of number of persons conducted and number of persons with morbidity has been reported.

The recorded morbidity for the year 1984 in the severe area is 96.87%, moderate area 97.40% mild area 98.62% compare to 0.06% for the control area. From the year 1991 onwards there is a gross reduction. Pulmonary morbidity uniformly observed in all exposed area. There by informing that the pulmonary morbidity was only due to a single time exposure area happening. In view of this whoever was exposed at with particular point of time demonstrated morbidity condition thereby resulting in sizable number of subjects coming out with the symptom of pulmonary morbidity.

By 1991 the same pulmonary morbidity started showing decline in terms of 76.642- 82.15% among the exposed area.

However, the percentage of morbidity remained at the higher level among the severely affected population when compare to moderate and mild. However over the years by 2010 the pulmonary morbidity insisted in the range of 9.81 to 17.29% in the affected areas. The reasons for percentage variation of pulmonary morbidity in 3 areas over the years are mainly because of large number of parameters influencing the movement of MIC gas cloud and how it traversed. These factors might be amount of release, it is concentration density, environmental condition in terms of temperature, humidity wind movement and velocity, wind direction, persistence of wind, availability of the concentration during the time of release how long the cloud transverse, how it affected population in different areas, ground level concentration the level at which the concentration were beyond the toxic limits the period of exposure, health condition of the individual at that time of time exposure and large number of relevant observations which can be accounted while assessing the individual exposure. It is extremely difficult to bring all these in to consideration for accounting individual morbidity. However it should be understood from the table that the pulmonary morbidity is a notable morbid condition still existing in the exposed areas which needs be looked into for initiating appropriate monitoring and intervention strategies.

Table-33 presents the details of eye morbidity rates observed during the years 1984-2010. The rate of morbidity was in the range of 98.08 to 99% during the year 1984 in all the 3 exposed areas. By 1991 in a span of 6 years it reduces to a range of 11.77 to 15.27. Subsequently by 2010 it was observed to be in the range of 9.39 to 15.85. This clearly indicates that the eye morbidity was also only at the time of the disaster which took place in 1984 it was only at the time of exposure to the toxic fumes which resulted in eye morbidity condition. There was no other influencing factor in extenuating eye problems over a period of time hence morbidity also showing the declining trend. Thereby it has stabilized the 9.392 to 15.8% in the exposed population. Even this eye morbidity conditions is 3-5% more among the exposed population when compare to the control which is significantly being demonstrated in the table.

Table-34 presents gastro intestinal tract morbidity rates observed during the year 1984 and 2010. It may be seen from the tables during 1984 the study morbidity was in the range of 15% to 73.5% among the exposed population. By 1991 it reduced to 5.88 to 7.99. By the year 2010 it is between 4.06 to 9.47%. Thereby indicating it may be a influence of one time exposure persisting for a long time over the years. When are to the prevalence of the similar morbidity it is 2 to 5% more in the exposed population. Persistent GIT morbidity might have been contributed by the drugs which have been advised for number of other ailments thereby it might have become persistent over the years in the exposed population.

Table 35-38 present the details of gastrointestinal symptoms in 4 areas for the period 1986-2010. It can be noticed the GIT symptoms include lack of appetite/loss of appetite, abdominal pain, constipation/passing of hard stools/diarrhoea, vomiting, epigastric burning and hematemesis/vomiting of blood. The tables also gives the details of persons who had more than one type of GIT symptoms in the form of total GIT symptoms recorded. Uniformly it can be observed that the morbidity in respect of abdominal pain and epigastric burning are very prominently seen in all the areas for the period 1986-2010. This particular symptom may be due to the influence of dietary habit, number of drugs being taken for different ailments and the influence of large number stressors. However, this needs to be assessed and closely monitored through clinical investigation to exactly pinpoint the risks and also to resort to suitable intervention measures to contain this symptom, which is persistently observed over a sizeable population. The comparison between 3 exposed areas and control further reveals the prevalence of abdominal pain is equally identified in control area almost with similar number of individuals complaining of the specific morbidity. However, the epigastric burning is significant.

Table – 39 gives the prevalence of skin morbidity rates observed during the year 1984-2010 the initial morbidity which was identified during 1984 subsequent to the disaster was in the range of 0.89 to 1.82%. Even during 2010 it is prevailing at 0.39 to 0.89% it is statistically insignificant($z=1.27, p>0.05$) When compare to the similar morbidity from the control it is not significant. Hence the skin morbidity cannot be considered as a contributed morbid condition due to 1984 disaster.

C= Contacted, M = No. of Morbid.

Supervisory and Working Staff (Centre for Rehabilitation Studies)

1. Dr.N.Banerjee Officer-in-charge

Assistant Research Officer (Medical)

1. Dr.B.S.Panwar
2. Dr.P.U.M.Rao
3. Dr.K.K.Soni
4. Dr.Ruma Galgalakar
5. Dr.Ajit Saluija

Computer & Statistical Officers

1. Dr.Sushil Singh R.O.
2. Mrs. Moina Sharma ARO
3. Dr. O.P.Tiwari (Expired) ARO

Secretarial Staff:

1. Sudhir Shrivastava, Section Officer
2. Mr.Mohan Waldurkar, Accountant
3. Mr.Krishnadas V.K. Senior Stenographer
4. Mr.R.Kerala varma Thampuran Junior Stenographer
5. Mrs.Anita S. Pillai Lower Division Clerk

Research Assistant

1. Mr. Abdul Mateen Khan
2. Mr.Mohd.Shoieb Khan
3. Mrs.Renuka Sen
4. Mrs.Rekha Yadav
5. Mr.V.S.Rathore
6. Mrs.Anita Shukla
7. Mr.D.S.Shukla
8. Mrs.Swapna Azahar
9. Mr.U.S.Chouhan
10. Mrs.Gouri Shrivastava(Retired)
11. Mr.Sudeep Shrivastava(Expired)
12. Mrs.Meena Chaturvedi
13. Mrs.Hemalata Saxena
14. Mrs.Anita Bhavsar
15. Mrs.Seema Khare
16. Mrs.Premalata Maheshwari (Retired)

17. Mr.D.S.Shukla
18. Mr.Rajendra Shrivastava
19. Mr.B.K.Dixit

Computer & Statistical Staff

1. Mr. Sanjajy Kumar Khare
2. Mr. Chandra Sekharan Pillai
3. Mr. Sunil Sharma
4. Mr. Anand Kori
5. Mr. Rajendra Kumar Pandey

Field Attendant

1. Miss. Aysha Khan
2. Mrs. Rukmani Lalwani
3. Mr. Mehfooz Ahmad
4. Mr. K.D. Sharma
5. Mr. M.P.Tiwari(Expired)

Class IV

1. Mr. Shrikant Mishra
2. Mr. Dilip Kumar Ugwae
3. Mr. Premlal Patwa
4. Mr. Abid Hussain
